Abstract

Over the past few years, data analytics has become increasingly important for companies across all industries. With the massive amount of data that is now available, companies can use data analytics to gain valuable insights into consumer behavior, market trends, and internal operations, among other things. As a result, data analytics has become a critical tool for companies looking to gain a competitive edge in today's rapidly evolving business environment. However, while data analytics has become an essential tool for businesses, there has been relatively little research done in the area of behavioral research. Specifically, there is a lack of research on the decision-making process involved in data analytics, and how individuals and organizations use data analytics to inform their decisions. One of the major challenges in conducting research in this area is the high cost of developing custom applications for each study. The development of such applications can be time-consuming, expensive, and often requires specialized expertise. To address this challenge, this master thesis develops a generic application that streamlines the process of conducting studies in the field of data analytics. This application enables researchers to design, conduct, and analyze studies more efficiently and cost-effectively, allowing them to explore the field in greater depth. This will be accomplished by using the design science research approach. Firstly, the problem of a lack of behavioral research in data analytics is identified. Then, the objectives for a solution are defined through a literature review and the use of requirement engineering to gather requirements for the application. Next, the application is design, implemented prototypically and its functionality demonstrated. Finally, solution is evaluated through the usages of the requirements.

1 Introduction

1.1 Background and Motivation

1.2 Research Problem and Objectives

1.3 Contribution and Scope of the Study

2 Theoretical foundations

This section represents the theoretical fundamentals of this elaboration by defining the terms “data analytic”, “information value chain”, and “boundaries and conflicts” as they are used in the context of this literature review.

2.1 Definition of terms

2.2 Data Analytics

The term “data analytics” originated in the early 2000s and describes an interdisciplinary field that combines areas such as statistics, machine learning, pattern recognition, system theory, operations research and artificial intelligence (Runkler, 2020). It can be generally defined “[...] as the application of computer systems to the analysis of large data sets for the support of decisions.” (Runkler, 2020). This definition showcases the broadness of the topic, as most computer systems process some amount of data and theoretically allow for some kind of decision making. Due to this broad definition, data analytics can cover slightly different subject areas depending on the context it is discussed in. In this elaboration, data analytics refers to the processing of large amounts of data, also referred to as “big data”, through mathematical procedures or machine learning methods with the goal of creating new knowledge. In summary, processes that merely prepare or show data are not considered data analytics, but only processes that process data in such a way that new knowledge can be derived from it. This distinction is made to differentiate data analytics from traditional data processing areas like business intelligence. The goal of data analytics, as is discussed in this literature review, is to retrieve some kind of previously unknown knowledge from a set of data. This process can be generally described using the “information value chain” model. In their research, Abbasi et al. analyze this model in the context of big data in an effort to create an inclusive research agenda for big data in information system research (Abbasi et al., 2016).

Figure 1: Information Value Chain

2.3 Information Value Chain

The information value chain (figure 1) is a set of phases that define the transformation of raw data to information and eventually into knowledge. “Data” describes raw facts without any structuring. Once organized, the processed data represents “information”. This “information” is then used to find patterns and draw conclusions. At this time, the information becomes knowledge (Fayyad et al., 1996a), Fayyad et al., 1996b. This knowledge is then used to make “decisions” and take corresponding “actions” (Sharma et al., 2014). Each phase of the information value chain also includes a different set of technologies and methodologies. For example, the “data” phase contains technologies and actions regarding the basic storage of data like database systems or data warehouses (Abbasi et al., 2016). The conventional version of this information value chain represents an approach that generally explains the processing of data. The main steps of this information value chain are also applicable for big data (Abbasi et al., 2016). This general structure of processing data is also supported by literature from the data analytics field (Runkler, 2020). In addition, the information value chain contains the further phases “decisions” and “actions”, which deal with the influence of the processed data. These phases reflect the impact of data analytics, since data analytics is primarily a technology for the decision-making process (Runkler, 2020). For this reason, the information value chain is a suitable model to structure different phases in the processing of data in the context of data analytics.

2.4 Boundaries and Conflicts in Organizations

This literature review uses the terms boundary and conflict interchangeably. In order to include as much literature as possible, the criteria for boundaries are kept very general. Prior to conducting the literature review, there was no formal definition of boundaries in the context of data analytics used for the selection of literature. Generally, boundaries are described as

“[...] a real or imagined line that marks the limits or edges of something and separates it from other things or places [...]” (Hornby, 2015). Based on this general description, the term boundary is defined in the context of this elaboration as any circumstance that leads to a reduction in the effectiveness or efficiency of an organization. Boundaries and conflicts are therefore used to describe any circumstance that hinders an organization from being perfectly productive. An example of such boundaries or conflicts would be communication issues between different departments, which lead to a reduction of productivity.

2.5 Design Science Research Methodology

2.6 Requirement Engineering

3 Identification of the Problem

3.1 Previous Studies and Gaps in the Literature

3.1.1 Literature Review: Behavioral Research in Data Analytics (on the basis of the Information Value Chain)

3.2 Applications (Anwendungen) for Behavioral Research

4 Definition of Objectives for a solution

4.1 Literature Review Studies in Data Analytics and General

4.2 requirements elicitation

4.2.1 Functional requirements

4.2.2 Functional requirements

4.2.3 Non-functional Requirements

4.3 Requirements analysis

5 Design and Dev artefacts

5.1 System Architecture and Components

5.2 User Interface Design and Implementation

5.3 Prototype Development

6 Demonstration of the Artifact

7 Evaluation of the solution

7.1 Prototype Testing

7.2 Requirements validation

7.3 (App Performance and Usability / User Feedback and Satisfaction)

8 Conclusion

8.1 Summary of the Study

8.2 Contributions and Implications

8.3 Future Work and Recommendations
